

The key goal here is to eventually prove the following results:

- Direct sums of exact sequences of (pre)sheaves on a topological space are exact.
- Direct products of epimorphisms of sheaves on X are not necessarily epimorphisms. (This is still incomplete. Once done, I'll append to the same link)
- Let \mathcal{T} be a triangulated category and \mathcal{L} be a localizing subcategory of \mathcal{T} . If $f : x \rightarrow y$ be a morphism in \mathcal{T} that is mapped to 0 by the projection $\mathcal{T} \rightarrow \mathcal{T}/\mathcal{L}$, then f factors through an object of \mathcal{L} .

Notation 1. For a topological space X , $\mathbf{Sh}(X)$ (resp. $\mathbf{PSh}(X)$) denotes the category of sheaves (resp. presheaves) of abelian groups over X .

Proposition 2. Let X be a topological space and I be a set. If for each $i \in I$,

$$0 \longrightarrow \mathcal{F}^i \longrightarrow \mathcal{G}^i \longrightarrow \mathcal{H}^i \longrightarrow 0$$

is an exact sequence in $\mathbf{PSh}(X)$, then,

$$0 \longrightarrow \bigoplus_i \mathcal{F}^i \longrightarrow \bigoplus_i \mathcal{G}^i \longrightarrow \bigoplus_i \mathcal{H}^i \longrightarrow 0$$

is also exact.

Proof. By assumption, for any open subset U of X ,

$$0 \longrightarrow \mathcal{F}^i(U) \longrightarrow \mathcal{G}^i(U) \longrightarrow \mathcal{H}^i(U) \longrightarrow 0$$

is exact. Since direct sums of exact sequences are exact in the category \mathbf{Ab} of abelian groups, the sequence

$$0 \longrightarrow \left(\bigoplus_i \mathcal{F}^i \right)(U) \longrightarrow \left(\bigoplus_i \mathcal{G}^i \right)(U) \longrightarrow \left(\bigoplus_i \mathcal{H}^i \right)(U) \longrightarrow 0$$

is exact. Thus, it follows that

$$0 \longrightarrow \bigoplus_i \mathcal{F}^i \longrightarrow \bigoplus_i \mathcal{G}^i \longrightarrow \bigoplus_i \mathcal{H}^i \longrightarrow 0$$

is exact. □

Proposition 3. Let X be a topological space and I be a set. If for each $i \in I$,

$$0 \longrightarrow \mathcal{F}^i \longrightarrow \mathcal{G}^i \longrightarrow \mathcal{H}^i \longrightarrow 0$$

is an exact sequence in $\mathbf{Sh}(X)$, then,

$$(1) \quad 0 \longrightarrow \bigoplus_i \mathcal{F}^i \longrightarrow \bigoplus_i \mathcal{G}^i \longrightarrow \bigoplus_i \mathcal{H}^i \longrightarrow 0$$

is also exact.

Proof. Let $U : \mathbf{Sh}(X) \rightarrow \mathbf{PSh}(X)$ denote the forgetful functor and $_^\dagger : \mathbf{Sh}(X) \rightarrow \mathbf{PSh}(X)$ denote the sheafification. Then, the sequence in Eq. (1) is isomorphic to the following sequence

$$0 \rightarrow \left(\bigoplus_i U(\mathcal{F}^i) \right)^\dagger \rightarrow \left(\bigoplus_i U(\mathcal{G}^i) \right)^\dagger \rightarrow \left(\bigoplus_i U(\mathcal{H}^i) \right)^\dagger \rightarrow 0$$

For any $x \in X$, since the forgetful and sheafification functors preserve stalks and since direct sums commute with colimits, applying the stalk functor $(_)_x$ yields (upto isomorphism) the following sequence

$$0 \longrightarrow \bigoplus_i \mathcal{F}_x^i \longrightarrow \bigoplus_i \mathcal{G}_x^i \longrightarrow \bigoplus_i \mathcal{H}_x^i \longrightarrow 0$$

which is exact since direct sums of exact sequences are exact in \mathbf{Ab} . □

Proposition 4. *Let \mathcal{T} be a triangulated category, \mathcal{L} a localising subcategory and $\mathcal{T}_{/\mathcal{L}}$ denote the Verdier quotient. A morphism $f : x \rightarrow y$ in \mathcal{T} is mapped to the zero morphism by the projection $\mathcal{T} \rightarrow \mathcal{T}_{/\mathcal{L}}$ if and only if f factors through an object in \mathcal{L} .*

Proof. Suppose that f is taken to 0 by the projection. That is, there exist $z, z' \in \mathcal{T}$, quasi-isomorphisms (relative to \mathcal{L}) σ, σ' and morphisms f', g, h in \mathcal{T} making the following diagram commute.

$$\begin{array}{ccccc}
 & & y & & \\
 & \nearrow f & \downarrow g & \searrow \text{Id} & \\
 x & \xrightarrow{f'} & z' & \xleftarrow{\sim \sigma'} & y \\
 & \searrow 0 & \uparrow h & \swarrow \sim \sigma & \\
 & & z & &
 \end{array}$$

Equivalently, there exists a quasi-isomorphism g such that $g \circ f = 0$. Hence, there exists a distinguished triangle of the following form in \mathcal{T}

$$y \xrightarrow{g} z \xrightarrow{\alpha} w \xrightarrow{\beta} \Sigma y$$

where $w \in \mathcal{L}$. By one of the axioms defining a (pre)triangulated category, there exists a dotted arrow $x \rightarrow \Sigma^{-1}w$ making the following diagram commute, thus yielding the required factorisation.

$$\begin{array}{ccccccc}
 \Sigma^{-1}x & \xrightarrow{\quad} & 0 & \xrightarrow{\quad} & x & \xrightarrow{\text{Id}} & x \\
 \downarrow \Sigma^{-1}f & & \downarrow 0 & & \downarrow \text{dotted} & & \downarrow f \\
 \Sigma^{-1}y & \xrightarrow{\Sigma^{-1}g} & \Sigma^{-1}z & \xrightarrow{\Sigma^{-1}\alpha} & \Sigma^{-1}w & \xrightarrow{-\Sigma^{-1}\beta} & y
 \end{array}$$

Conversely, suppose that f factors as in the following diagram, where $w \in \mathcal{L}$.

$$\begin{array}{ccc}
 x & \xrightarrow{f} & y \\
 \searrow \alpha & & \nearrow \beta \\
 & w &
 \end{array}$$

As previously argued, it is sufficient to show that there exists a quasi-isomorphism g such that $g \circ f = 0$. By one of the axioms defining a (pre)triangulated category, there exists a diagram of the following form, where the rows are distinguished and there is a dotted arrow that completes the morphism of distinguished triangles.

$$\begin{array}{ccccccc}
 x & \xrightarrow{f} & y & \longrightarrow & \text{cone}(f) & \longrightarrow & \Sigma x \\
 \downarrow \alpha & & \parallel & & \downarrow \text{dotted} & & \downarrow \Sigma \alpha \\
 w & \xrightarrow{\beta} & y & \longrightarrow & \text{cone}(\beta) & \longrightarrow & \Sigma w
 \end{array}$$

We take the morphism $y \rightarrow \text{cone}(\beta)$ in the above diagram to be g . □
